Planning Parking Building Using Flat Slab and Drop Panel as a Replacement Conventional Beam with Analyzing Bending Moment Value & Sliding Style Based On SNI 1726-2012

Agyanata Tua Munthe and Guntur Jatmiko
Civil Engineering, Mercu Buana University, Jl. Raya Kranggan No.6, Jawa Barat, Indonesia
agyanata.umb@gmail.com, gunturjatmiko@gmail.com

Abstract

The construction of a 5-stored parking building is planned to use a flat slab (with drop panels). Flat slab (with drop panel) is a type of two-way plate without beams that directly rests on the column, the flat slab can reduce the height of the structure and construction time. However, flat slabs require plates that are thicker than usual to overcome deflection and punching shears. In this final project, a 5-story reinforced concrete structure will be reviewed with a span of 8 x 8.3 m. Analysis and design was carried out with the help of the 2016 ETABS program to find the value of intersection between floors, shear moments and forces taking into account the consequences of dead load, super dead load, life, and earthquake (dynamic).

Keyword: flat slab, drop panel, parking building, planning

1. Introduction

In developing countries like Indonesia, especially in Jakarta with very high mobility, the use of vehicles is very much needed starting from private and public vehicles. At present, the use of private vehicles is still in demand by some people on a more flexible basis because they can walk at any time without having to wait like public transportation. Then the ratio is not balanced between the increasing population of vehicles with available parking space, given that the vacant land in Jakarta is decreasing because it is used for residential and office space, which sometimes has insufficient parking space. So one solution is to build a multi-storey parking building so that it can accommodate a large number of vehicles. In this parking building there are elements consisting of columns, flat slabs with drop panels. All elements are made of reinforced concrete. Reinforced concrete is a concrete reinforced with an area and the number of reinforcement that is not less than the minimum value required with or without prestressing, and is planned based on the assumption that the two materials work together in bearing forces. Flat slabs are thick, evenly thick concrete slabs that transfer loads directly to supporting columns without the help of beams (McCormac, 2000). Drop panel is an increase in the thickness of the plate in the column area that serves to reduce the shear stress caused by the column against the plate. The use of flat slabs with this drop panel system will increase the magnitude of the moment of resistance in places where the negative moments are (More and sawant, 2015). The use of flat slab with this drop panel system will increase the strength of the plate against shear and flexural force and can withstand heavy loads and longer spans.

While the purpose of this research is:
1) Find out how many intersections between floors of the building design
2) Knowing the number of bending moments and shear forces of the building design

2. Research methods

Using analysis methods in structural modeling using the 2016 ETABS program to find the value of bending moment and shear force by referring to applicable regulations such as SNI 1726-2012, SNI 1727-2013, SNI 2847-2013. The flowchart of the study in this study is as follows:
3. Result and Discussion

Research Analysis Stage

1. Geometry Structure:
   ✓ Building function: Parking building
   ✓ Number of floors: 5 floors (split level)
   ✓ Height per floor: 3m
   ✓ Soil type: Medium soil (SD)

2. Material Quality:
   ✓ Reinforced concrete, f'c 35MPa for flat slabs, drop panels, beams and f'c 45MPa for columns
   ✓ Reinforcing steel, Ø8, Ø10, Ø12 mm plain reinforcement BJTP-24 with 240 MPa fy. D10, D13, D16, D19, D22, D25 mm BJTD-40 screw reinforcement with fy 400 MPa. And the specific gravity of the iron used is 7850 Kg/m³

3. Existing Dimensions:
   ✓ For Beam B1 (300x500), column K1 (1200x1200) dan K2 (900x900)

4. Loading:

Figure 1. Research Flowchart
Dead load, self weight of its structure (calculated automatically by Etabs)
Gravitas Gravity load is divided into two, namely dead load (installation ME = 0.25 kN/m² & waterproofing with asphalt = 0.28 kN/m²) and live load (for parking is set 2 kN/m²)
Gravitas The gravity load on the slap parapet area is equal to 21.6 kN/m²
5. Preliminary plates:
   Flat slab:
   - Thickness of directional plates Y, L=9000mm (the longest size)
     Clean plate length => 9000 – 600 = 8400mm
     For external panels, a minimum thickness of plates => 8400 / 33 = 254.54mm
     For panels in a minimum thickness of plates => 8400 / 36 = 233.3mm
     The thickness of the plate to be used 260mm
   - Thickness of directional plates X, L=8000mm (the longest size)
     Clean plate length => 8000 – 600 = 7400mm
     For external panels, a minimum thickness of plates => 7400 / 33 = 224.24mm
     For panels in a minimum thickness of plates => 7400 / 36 = 205.5mm
     The thickness of the plate to be used 230mm
     From the 2 directions Y and X, the largest value is taken 260mm
   - Thickness drop panel => 260 / 4 = 65. Then 260mm + 65mm = 325mm
   - Determine the extension of the area of the panel drop area with the longest formula L between columns divided by 6.
6. Earthquake load (E) - elastic earthquake response:

   From the Puskim the following data are obtained:

<table>
<thead>
<tr>
<th>Ss</th>
<th>Fs</th>
<th>SsDS</th>
<th>SsD1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.669</td>
<td>1.265</td>
<td>0.564g</td>

</tr>
<tr>
<td>0.295</td>
<td>1.811</td>
<td>0.356g</td>
<td></td>
</tr>
</tbody>
</table>

   The design category is determined by value SsDS dan SsD1 that is type D
   Vibration period, T0 = 0.126 dt dan T = 0.631 dt

   Design calculation
   - The value of the fundamental period => T_x = 0.533 second & T_y = 0.746 second
   - Period The period value of Etabs => T_x = 0.708 second & T_y = 0.659 second (OK)
   - Seismic response coefficient values => C_x = 0.0785 & C_y = 0.0844
   - The weight value of the building structure => 70389.82 kN
   - Value of basic seismic shear forces => V_x = 5525.6 kN & V_y = 5940.9 kN
   - Exponent value (k) => T_x = 1.104 & T_y = 1.07
   - Lateral earthquake force values => F_x = 5525.6 kN & F_y = 5940.9 kN
   - Selection of types => 4.9 % entered into CQC
   - Basic shear force scale => E_x = 1594.897 & E_y = 1678.047
   - Intersection between floors due to earthquake loads X and Y

- **Reinforcement calculation steps**

1. 1-way slide check for critical cross sections A-A (X)

   \[
   Vu = 312,855 \text{ kN} = 31.9 \text{ ton}
   \]

   \[
   \varnothing Vc = 0.75 \times \sqrt{\frac{f'c}{6}} \times b \times d
   \]

   \[
   \varnothing Vc = 0.75 \times \sqrt{\frac{35}{6}} \times 8 \times 0.233 = 137.84 \text{ ton}
   \]

   \[
   Vu < \varnothing Vc (OK)
   \]
1-way slide check for critical cross sections B-B (Y)

\[ Vu = 319,506 \text{ kN} = 32.58 \text{ ton} \]

\[ \emptyset V_c = 0.75 \times \sqrt{\frac{f_c'}{6}} \times b \times d \]

\[ \emptyset V_c = 0.75 \times \sqrt{\frac{35}{6}} \times 8.3 \times 0.233 = 143.01 \text{ ton} \]

\[ Vu < \emptyset V_c \text{ (OK)} \]

Check 2-way slide

\[ Vu = 319,506 \text{ kN} = 32.58 \text{ ton} \]

\[ Bc = 900/900 = 1 \]

\[ as = 40 \]

\[ b_o = 2 \times (1016.75 + 1016.75) = 4067 \text{ mm} = 4.067 \text{ m} \]

\[ V_{c(a)} = \frac{1}{3} \times (1 + \frac{2}{Bc}) \times \sqrt{f_c'} \times b_o \times d = \frac{1}{3} \times \sqrt{35} \times 4.067 \times 2.33 = 280 \text{ ton} \]

\[ V_{c(b)} = \left( \frac{as \times d + \frac{1}{6}}{12 \times 4.067} \right) \times \sqrt{f_c'} \times b_o \times d = \frac{1}{3} \times \sqrt{35} \times 4.067 \times 0 \times 233 = 200 \text{ ton} \]

\[ V_{c(c)} = \frac{1}{3} \times \sqrt{f_c'} \times b_o \times d = \frac{1}{3} \times \sqrt{35} \times 4.067 \times 0 \times 186 = 186 \text{ ton} \]

Take the smallest \( V_c \) value, such that

\[ \emptyset V_c = 0.75 \times 186 = 139.5 \text{ ton} \]

Then,

\[ Vu = 32.58 \text{ ton} < \emptyset V_c = 139.5 \text{ ton} \], the plate shear capacity is sufficient to carry two-way shear

Calculate the effective height of a floor plate (d)

Concrete blanket for floor plates 20mm (t_s)

Principal reinforcement used D13mm

\[ d = h - t_s - 0.5 \times D = 260 - 20 - 0.5 \times 13 = 233.5 \text{ mm (long direction)} \]

\[ d = h - t_s - D - 0.5 \times D = 260 - 20 - 13 - 0.5 \times 13 = 220.5 \text{ mm (short direction)} \]

Calculate the value \( \beta_1 \)

For \( f_c \leq 30 \text{ MPa} \), \( \beta_1 = 0.85 \)

For \( 30 < f_c < 55 \text{ MPa} \), \( \beta_1 = 0.85 - 0.008 \times (f_c - 30) \)

For \( f_c > 55 \text{ MPa} \), \( \beta_1 = 0.65 \)

Then,

\[ f_c = 35 \text{ MPa}, \beta_1 = 0.85 - 0.008 \times (35 - 30) = 0.81 \]

\[ \rho_b = \frac{0.85 \times 0.81 \times f_c'}{fy} \left( \frac{600}{600 + fy} \right) = \frac{0.85 \times 0.81 \times 35}{400} \left( \frac{600}{600 + 400} \right) = 0.0361 \]

Calculate the amount of the minimum and maximum reinforcement ratio

\[ \rho_{\text{min}} = 0.0018 \text{ (bersumber SNI 2847:2013 pasal 7.12.2.1)} \]

\[ \rho_{\text{max}} = 0.75 \times \rho_b = 0.75 \times 0.0361 = 0.027 \]

Calculating the reinforcement of the column shortening direction (pedestal)

Calculation of the principal reinforcement in the column lane area uses reinforcement D 13 mm.

\[ M_n = \left( \frac{M_0}{\phi} \right) = \left( \frac{312,855}{0.9} \right) = 347.62 \text{ kNm} \]

\[ R_n = \left( \frac{M_n}{b \times d^2} \right) = \left( \frac{347610000}{1000 	imes 220.5^2} \right) = 7.15 \]

\[ m = \left( \frac{0.85 \times f_c'}{fy} \right) = \left( \frac{0.85 \times 35}{400} \right) = 13.45 \]

Reinforcement ratio
\[ \rho = \frac{1}{m} \left[ 1 - \sqrt{1 - \frac{2(m)(R_n)}{f_y}} \right] \]
\[ \rho = \frac{1}{13.45} \left[ 1 - \sqrt{1 - \frac{2(13.45)(0.36)}{400}} \right] = 0.0208 \]

Area reinforcement needed
As min = \( \rho \times b \times t \) = 0.0018 \( \times \) 1000 \( \times \) 260 = 468 mm²
As = \( \rho \times b \times d \) = 0.0208 \( \times \) 1000 \( \times \) 220.5 = 4581.067 mm²
Then used As = 4581.067 mm²

Distance between reinforcement
\[
S = \left( \frac{0.25 \pi \varphi^2 \times b \times t}{\bar{A}_s} \right) = \left( \frac{0.25 \times \pi \times 3.14 \times 1 \times 3^2 \times 1000}{4581.067} \right) = 28.95 \text{ mm} - 30 \text{ mm} \]
\[
S = \left( \frac{0.25 \pi \varphi^2 \times b \times t}{\bar{s}} \right) = \left( \frac{0.25 \times \pi \times 3.14 \times 1 \times 3^2 \times 1000}{30} \right) > 30 \text{ mm} (OK) \]
Then the reinforcement of column lane shortening (Footing) is used = D13 - 30 mm

- Calculate the reinforcement of the column shortening direction (field)
Calculation of the principal reinforcement in the column lane area uses reinforcement D 13 mm.
\[ M_o = 15.657 \text{ kNm} \]
\[ M_n = \left( \frac{M_o}{\varphi} \right) = \left( \frac{15.657}{0.9} \right) = 17.4 \text{ kNm} \]
\[ R_n = \left( \frac{M_n}{b \times d^2} \right) = \left( \frac{1740000}{1000 \times 220.5^2} \right) = 0.36 \]
\[ m = \left( \frac{f_y}{0.85 \times f'c} \right) = \left( \frac{400}{0.85 \times 35} \right) = 13.45 \]
Reinforcement ratio
\[ \rho = \frac{1}{m} \left[ 1 - \sqrt{1 - \frac{2(m)(R_n)}{f_y}} \right] \]
\[ \rho = \frac{1}{13.45} \left[ 1 - \sqrt{1 - \frac{2(13.45)(0.36)}{400}} \right] = 0.0009 \]
Area reinforcement needed
As min = \( \rho \times b \times t \) = 0.0018 \( \times \) 1000 \( \times \) 260 = 468 mm²
As = \( \rho \times b \times d \) = 0.0009 \( \times \) 1000 \( \times \) 220.5 = 198,442 mm²
Because As min > As, then used As min = 468 mm²

Distance between reinforcement
\[
S = \left( \frac{0.25 \pi \varphi^2 \times b \times t}{\bar{A}_s} \right) = \left( \frac{0.25 \times \pi \times 3.14 \times 1 \times 3^2 \times 1000}{468} \right) = 283.47 \text{ mm} - 290 \text{ mm} \]
\[
S = \left( \frac{0.25 \pi \varphi^2 \times b \times t}{\bar{s}} \right) = \left( \frac{0.25 \times \pi \times 3.14 \times 1 \times 3^2 \times 1000}{290} \right) > 290 \text{ mm} (OK) \]
Then used the direction of the column shortening direction column (Field) = D13 - 290 mm

- Calculate the reinforcement of the shortened center lane (pedestal)
Calculation of the principal reinforcement in the column lane area uses reinforcement D 13 mm.
\[ M_o = 13,235 \text{ kNm} \]
\[ M_n = \left( \frac{M_o}{\varphi} \right) = \left( \frac{13,235}{0.9} \right) = 14.71 \text{ kNm} \]
\[ R_n = \left( \frac{M_n}{b \times d^2} \right) = \left( \frac{1471000}{1000 \times 220.5^2} \right) = 0.30 \]
\[ m = \left( \frac{f_y}{0.85 \times f'c} \right) = \left( \frac{400}{0.85 \times 35} \right) = 13.45 \]
Reinforcement ratio
\[ \rho = \frac{1}{m} \left[ 1 - \sqrt{1 - \frac{2(m)(R_n)}{f_y}} \right] \]
\[ \rho = \frac{1}{13.45} \left[ 1 - \sqrt{1 - \frac{2(13.45)(0.30)}{400}} \right] = 0.0028 \]
\[ \rho = \frac{1}{m} \left[ 1 - \sqrt{1 - \frac{2(m)(R_n)}{f_y}} \right] \]
\[ \rho = \frac{1}{13.45} \left[ 1 - \sqrt{1 - \frac{2(13.45)(0.8)}{400}} \right] = 0.0008 \]

Area reinforcement needed
As \( \text{min} = \rho_g \times b \times t \) = 0.0018 \times 1000 \times 260 = 468 mm²
As \( = \rho \times b \times d \) = 0.0008 \times 1000 \times 220.5 = 167.586 mm²
Because \( As \text{ min} > As \), then used \( As \text{ min} = 468 \text{ mm}^2 \)

Distance between reinforcement
\( S = \left( \frac{0.25 \times \pi \times \varphi^2 \times b}{A_s} \right) \left( \frac{0.25 \times 3.14 \times 1 \times 3^2 \times 1000}{468} \right) = 283.47 \text{ mm} \sim 290 \text{ mm} \)
\( S = \left( \frac{0.25 \times \pi \times \varphi^2 \times b}{s} \right) \left( \frac{0.25 \times 3.14 \times 1 \times 3^2 \times 1000}{290} \right) = 457.46 > 290 \text{ mm (OK)} \)

Maka digunakan tulangan arah memendek lajur tengah (Tumpuan) = D13 - 290 mm

- Calculate the shortened center lane reinforcement (field)
- Calculation of the main reinforcement in the column path are D 13 mm.
  \( M_o = 12,521 \text{ kNm} \)
  \( M_n = \frac{M_o}{\varphi} = \frac{12,521}{0.9} = 13,91 \text{ kNm} \)
  \( R_n = \frac{M_n}{b \times d^2} = \frac{147,1000}{1000 \times 220.5} = 0.29 \)
  \( m = \frac{0.85 \times f_y}{f'_c} = \frac{400}{0.85 \times 35} = 13.45 \)
- Reinforcement ratio
  \[ \rho = \frac{1}{m} \left[ 1 - \sqrt{1 - \frac{2(m)(R_n)}{f_y}} \right] \]
  \[ \rho = \frac{1}{13.45} \left[ 1 - \sqrt{1 - \frac{2(13.45)(0.29)}{400}} \right] = 0.0007 \]
- Area reinforcement needed
  As \( \text{min} = \rho_g \times b \times t \) = 0.0018 \times 1000 \times 260 = 468 mm²
  As \( = \rho \times b \times d \) = 0.0007 \times 1000 \times 220.5 = 158.501 mm²
  Because \( As \text{ min} > As \), then used \( As \text{ min} = 468 \text{ mm}^2 \)
- Distance between reinforcement
  \( S = \left( \frac{0.25 \times \pi \times \varphi^2 \times b}{A_s} \right) \left( \frac{0.25 \times 3.14 \times 1 \times 3^2 \times 1000}{468} \right) = 283.47 \text{ mm} \sim 290 \text{ mm} \)
  \( S = \left( \frac{0.25 \times \pi \times \varphi^2 \times b}{s} \right) \left( \frac{0.25 \times 3.14 \times 1 \times 3^2 \times 1000}{290} \right) = 457.46 > 290 \text{ mm (OK)} \)

Then used the direction bar shortening the middle lane (Field) = D13 - 290 mm

✓ Recap the flat slab reinforcement is shortened (X)

Flat slab reinforcement image shortening (X) and longitudinal direction (Y)

Drop The reviewed panel drop area and the moment output from etabs
1-way slide check for critical cross sections A-A (X)

\[ V_u = 232,261 \text{ kN} = 23,684 \text{ ton} \]

\[ V_c = 0.75 \times \sqrt{\frac{f'_c}{6}} \times b \times d \]

\[ V_c = 0.75 \times \sqrt{\frac{35}{6}} \times 2.8 \times 0.289 = 59.84 \text{ ton} \]

\[ V_u < V_c \text{ (OK)} \]

1-way slide check for critical cross sections B-B (Y)

\[ V_u = 182,826 \text{ kN} = 18,64 \text{ ton} \]

\[ V_c = 0.75 \times \sqrt{\frac{35}{6}} \times b \times d \]

\[ V_c = 0.75 \times \sqrt{35/6} \times 2.8 \times 0.289 = 59.84 \text{ ton} \]

\[ V_u < V_c \text{ (OK)} \]

Check 2-way slide

\[ V_u = 232,261 \text{ kN} = 23,684 \text{ ton} \]

\[ B_c = 900/900 = 1 \]

\[ a_s = 40 \]

\[ b_o = 2 \times (1044.5 + 1044.5) = 4,178 \text{mm} = 4,2 \text{mm} \]

\[ V_{c(a)} = \frac{1}{6} \times (1 + \frac{a_s}{B_c}) \times \sqrt{f'_c} \times b_o \times d \]

\[ V_{c(a)} = \frac{1}{6} \times (1 + \frac{40}{900}) \times \sqrt{35} \times 4.2 \times 0.289 = 359 \text{ ton} \]

\[ V_{c(b)} = \frac{1}{6} \times \left( \frac{12b_o + 1}{6} \right) \times \sqrt{f'_c} \times b_o \times d \]

\[ V_{c(b)} = \left( \frac{12 \times 2.8 + 1}{6} \right) \times \sqrt{35} \times 4.2 \times 0.289 = 284.34 \text{ ton} \]

\[ V_{c(c)} = \frac{1}{3} \times \sqrt{f'_c} \times b_o \times d \]

\[ V_{c(c)} = \frac{1}{3} \times \sqrt{35} \times 4.2 \times 0.289 = 239.4 \text{ ton} \]

Take the smallest \( V_c \) value, such that

\[ V_c = 0.75 \times 239.4 = 179.55 \text{ ton} \]

Then, \( V_u = 23,684 \text{ ton} < V_c = 179.55 \text{ ton} \), the plate shear capacity is sufficient to carry two-way shear.

Calculate the effective height of the floor plate (d) Selimut beton untuk pelat lantai 20mm (t). Main reinforcement used D16mm

\[ d = h - t_s - D \]

\[ d = 325 - 20 - 16 = 289 \text{ mm (lajur kolom)} \]

\[ d = h - t_s - D \]

\[ d = 260 - 20 - 16 = 224 \text{ mm (lajur tengah)} \]

Calculate the value \( \beta_1 \)

For \( f'_c \leq 30 \text{ MPa} \), \( \beta_1 = 0.85 \)

For \( 30 < f'_c < 55 \text{ MPa} \), \( \beta_1 = 0.85 - 0.008 ( f'_c - 30 ) \)

For \( f'_c > 55 \text{ MPa} \), \( \beta_1 = 0.65 \)

Then, \( f'_c = 35 \text{ MPa} \), \( \beta_1 = 0.85 - 0.008 ( 35 - 30 ) = 0.81 \)

\[ \rho_b = \frac{0.85 \times \beta_1 f'_c}{f_y} \left( \frac{600}{600 + f_y} \right) = \frac{0.85 \times 0.81 \times 35}{400} \left( \frac{600}{600 + 400} \right) = 0.0361 \]

Calculate the amount of the minimum and maximum reinforcement ratio \( \rho_g = 0.0018 \) (based on SNI 2847:2013 pasal 7.12.2.1)

\[ \rho_{max} = 0.75 \times \rho_b = 0.75 \times 0.0361 = 0.027 \]

Calculating the reinforcement of the column shortening direction (pedestal)

Calculation of the principal reinforcement in the column lane area uses reinforcement D 16 mm.

\[ M_o = 232,261 \text{ kNm} \]
\[ M_n = \left( \frac{M_0}{\phi} \right) = \left( \frac{232.261}{0.9} \right) = 258,067 \text{ kNm} \]

\[ R_n = \left( \frac{M_n}{1000 \times 289^2} \right) = \left( \frac{258067000}{1000 \times 289^2} \right) = 3.09 \]

\[ m = \left( \frac{f_y}{0.85 \times f'c} \right) = \left( \frac{400}{0.85 \times 35} \right) = 13.45 \]

Reinforcement ratio

\[ \rho = \frac{1}{m} \left[ 1 - \sqrt{1 - \frac{2(m)(R_n)}{f_y}} \right] \]

\[ \rho = \frac{1}{13.45} \left[ 1 - \sqrt{1 - \frac{2(13.45)(3.09)}{400}} \right] = 0.0082 \]

Area reinforcement needed

As \( \text{min} = \rho_g \times b \times t = 0.0018 \times 1000 \times 325 = 585 \text{ mm}^2 \)

As \( = \rho \times b \times d = 0.0082 \times 1000 \times 289 = 2369.8 \text{ mm}^2 \)

Then used \( As = 2369.8 \text{ mm}^2 \)

Distance between reinforcement

\[ S = \left( \frac{0.25 \times \pi \times b \times t^2}{2} \right) = \left( \frac{0.25 \times 3.14 \times 3 \times 1 \times 6^2 \times 1000}{2} \right) = 84.8 \text{ mm} \sim 90 \text{ mm} \]

\[ As = \left( \frac{0.25 \times \pi \times b \times t^2}{5} \right) = \left( \frac{0.25 \times 3.14 \times 3 \times 1 \times 6^2 \times 1000}{90} \right) = 223.2 > 90 \text{ mm(OK)} \]

Then the reinforcement of column lane shortening (Footing) is used = D16 - 90 mm

**Then use the same steps as the calculation in the slab**

✓ Recap the shortening direction drop bar reinforcement (X)

✓ Image of reinforcement drop panel shortening (X) and longitudinal direction (Y)
4. Conclusion

a. Conclusion

From the results and analysis of flat slab and drop panel calculations can be concluded:

1. This parking building with flat slab and Drop panel 5 floors is feasible to use because the intersection between floors is 0.10mm for X direction and 0.008mm for Y direction taken on average from 5 floors. This value is below the permit value limit of 22.5cm.

3. The smallest panel drop size from 1650x1950mm to 2800x3000mm (floor plan attached).

4. For the biggest moment value on the P3A floor with:
   - M max direction X = 32,285
   - M min direction X = -588,671
   - M max direction Y = 328,179
   - M min direction Y = -702,975

5. For flat slabs, slide one-way cross section critical A-A (X), Vu <∅Vc (OK) => 31.9 tons <137.84 tons. For one-way sliding critical cross sections B-B (Y), Vu <∅Vc (OK) => 32.58 tons <143.01 tons. For the two-way cross section critical A-A (X), Vu <∅Vc (OK) => 32.58 tons <139.5 tons.

6. For drop panels, slide one-way critical cross sections A-A (X), Vu <∅Vc (OK) => 23,684 tons <59.84 tons. For one-way sliding critical cross section B-B (Y), Vu <∅Vc (OK) => 18.64 tons <59.84 tons. For the two-way sliding cross section critical A-A (X), Vu <∅Vc (OK) => 23,684 tons <179.55 tons.

b. Suggestion

For further research development regarding flat slabs and drop panels, it is recommended to:

1. In this Final Project do not try various assumptions about the thickness of the flat slab and drop panel due to time constraints. Maybe this can be a material for further researchers to conduct more detailed research in order to obtain an efficient thickness.

2. Taking into account the use of shear reinforcement, such as shear stud or structural shearhead on flat plates and flat slabs (drop panels).

3. Calculating the reinforcement ratio.
